Legal Intake Implementation

Jira Service Management and Confluence

Practice case | Jun Ming Law Firm | February 2025 to present

I administered legal intake for a remote law practice across time zones. My work covered request configuration, change testing, user guidance and reporting. I also maintained the Confluence knowledge base that supported the practice.

Two intake contexts

Request context	Operating scope
Client to law firm	Requests from clients to the firm for legal support.
Internal company to legal team	Requests from employees of a client company to its legal team.

Configuration and change testing

I configured request forms, fields, queues and workflows, including automation for notifications and deadline reminders. Before release, I tested changes with trial requests, traced configuration errors and corrected them. I documented configuration changes so the setup could be maintained.

Knowledge and user support

I maintained templates, checklists, SOPs, self-service FAQs and legal guidance in Confluence. Content went to its owner for confirmation before publication; I set page permissions and removed or archived outdated content. I trained users to submit and track their requests. The knowledge work supported recurring questions and gave users written procedures they could return to.

Monitoring and maintenance

I used JSM reports and dashboards to monitor request volume and handling time. Based on those reports and user feedback, I revised form fields and queue or assignment rules, and where requests stalled, I added notifications or deadline reminders. I maintained the configuration alongside the supporting instructions.

The following page illustrates how I would document a configuration change and its acceptance checks using fictional requests.

Configuration and Testing

Fictional requests and proposed settings

This example specifies an intake change before configuration. The field names, routes and checks below are proposed settings. The checks describe expected results and have not been executed in a Jira instance for this sample.

Define the intake record

On submission: requester, organization, intake context, request type, short description, requested completion date and deadline basis. For contract review, capture the draft or document location. During triage: assigned reviewer, next action, review status and any confirmed legal deadline.

Specify behavior and test it

Scenario	Proposed behavior	Acceptance check
Document missing	If both the draft and its location are missing, request the document and set Needs information.	Submit a contract request without a draft or document link. Confirm its status and information request.
Ready for triage	Make complete, unassigned requests visible in the legal triage queue.	Submit a complete request. Confirm queue membership and that no approval is recorded.
Reminder due	For an open, assigned request at the configured reminder time, notify its reviewer.	Check time-zone handling, intended recipient and the automation audit log.
Guidance linked	Link the relevant maintained Confluence guidance where the requester has access.	Use permitted and restricted test accounts. Check both the request and article visibility.

Keep routing separate from authority

Queues identify work for review. Access permissions need separate configuration and testing. A requested completion date needs its deadline basis checked; legal approval and authority to sign remain explicit decisions.

Record the change and hand it over

Keep the changed settings, rule owner and actor, trial-request IDs, expected and observed results, audit-log references, unresolved defects and the prior configuration needed to revert. Update the submission guide and record who will maintain the rules and Confluence content.
